Webhook trading is plumbing, not a button

A webhook looks simple from the outside: one URL receives one message. In trading, that message needs strict structure. The receiving system must know who sent it, which account it belongs to, which platform should execute it, and which action is allowed.

This deck is a new Archive version written separately for Webhook.trade.

Why raw webhooks break in real accounts

A raw TradingView alert can be enough for a demo. Live automation needs more context. The same ticker may require a suffix, the same action may require hedge or reverse handling, and the same quantity may mean different things across platforms. Webhook.trade exists to explain these practical details.

Common failure

The webhook arrives, but the payload is not specific enough for the execution venue.

Ticker rules

Symbols should match the platform naming rule, not only the chart label.

Action rules

Open, close, flat, reverse, and opposite logic must be explicit.

Account rules

A webhook must be tied to the correct user, platform, and account context.

The value of a clear JSON schema

Webhook trading becomes safer when the payload is predictable. A schema forces the sender to include the right fields and prevents vague messages from reaching execution. This is especially useful when alerts come from TradingView, custom scripts, Telegram parsers, or external tools.

Structured input

A connector should reject unclear messages before they become orders.

Required fields

Platform, ticker, action, and quantity need stable names.

Optional fields

Stops, targets, trailing values, and metadata should be handled deliberately.

Validation

Bad or missing data should produce a useful error, not a silent failure.

How Webhook.trade supports the AlgoWay story

Webhook.trade is a clean topic site for explaining webhook trading. AlgoWay is the execution connector behind more advanced workflows. Together they cover the route from webhook concept to real routing: signal input, validation, decision, platform handling, and logging after the execution request.

Content role

The domain can educate visitors who search for webhook trading before they know which connector they need.

Education

Explain alerts, payloads, schema, endpoint security, and execution logging.

Routing

Show why one URL can still need platform-specific decisions.

Conversion

Move readers from concept pages into AlgoWay automation pages.

What a trader should check before publishing a webhook URL

The URL is not the strategy. It is an entry point. Before using it live, the trader should confirm payload fields, platform mapping, account status, order size rules, and how the connector reports rejected or filled orders. These checks are small, but they protect the account from avoidable mistakes.

Operational detail

Webhook security is also operational: the endpoint should accept the right payload from the right source and ignore the rest.

Payload preview

Send a test message and inspect exactly what the server receives.

Execution route

Verify which platform and account the signal will use.

Error visibility

Keep a clear message for rejected, expired, disabled, or malformed requests.

Reference link for webhook trading notes

Webhook.trade is the natural reference point for short explanations about webhook trading, TradingView alerts, JSON payloads, endpoint routing, and the practical connection between signals and AlgoWay execution workflows.

Anchor

A link from Archive should use a contextual anchor such as webhook trading automation or Webhook.trade.
